CYANO-SUBSTITUTED DIHYDROPYRIMIDINE COMPOUNDS AND THEIR USE TO TREAT DISEASES

RELATED APPLICATIONS

This application claims the benefit under 35 U.S.C. Section 119(e) of U.S. Provisional Patent Application No. 60/279,956 filed March 29, 2001.

FIELD OF INVENTION

This invention relates to novel compounds that interrupt mitosis thereby making the compounds useful for the treatment of proliferative diseases, such as cancer.

BACKGROUND

Cell proliferation and programmed cell death play important roles in the growth and development of an organism. In proliferative diseases such as cancer, the processes of cell proliferation and/or programmed cell death are often perturbed. For example, a cancer cell may have unregulated cell division through either the overexpression of a positive regulator of the cell cycle or the loss of a negative regulator of the cell cycle, perhaps by mutation. Alternatively, a cancer cell may have lost the ability to undergo programmed cell death through the overexpression of a negative regulator of apoptosis. Hence, there is a need to develop new chemotherapeutic drugs that will restore the processes of checkpoint control and programmed cell death to cancerous cells.

One approach to the treatment of human cancers is to target a protein that is essential for cell cycle progression. In order for the cell cycle to proceed from one phase to the next, certain prerequisite events must be completed. There are checkpoints within the cell cycle that enforce the proper order of events and phases. One such checkpoint is the spindle checkpoint that occurs during the metaphase stage of mitosis. Small molecules that target proteins with essential functions in mitosis may initiate the spindle checkpoint to arrest cells in mitosis. Of the small molecules that arrest cells in mitosis, those which display anti-tumor activity in the clinic also induce apoptosis, the morphological changes associated with programmed cell death.

An effective chemotherapeutic for the treatment of cancer may be one that induces checkpoint control and subsequent programmed cell death.

Most compounds known to cause mitotic arrest and apoptosis act as tubulin binding agents. These compounds alter the dynamic instability of microtubules and indirectly alter the function/structure of the mitotic spindle thereby causing mitotic arrest. Because most of these compounds target the tubulin protein, a component of all microtubules, they may also affect normal cellular processes in which microtubules have a role. Hence, a need exists for small molecules that specifically target proteins associated with proliferating cells, such as Eg5.

Eg5 is one of several kinesin-like motor proteins that are localized to the mitotic spindle and known to be required for formation and/or function of the bipolar mitotic spindle. Recently, there was a report of a small molecule that disturbs bipolarity of the mitotic spindle (Mayer, T.U. et. al. 1999. Science 286(5441) 971-4). More specifically, the small molecule induced the formation of an aberrant mitotic spindle wherein a monoastral array of microtubules emanated from a central pair of centrosomes, with chromosomes attached to the distal ends of the microtubules. The small molecule was dubbed "monastrol" after the monoastral array. This monoastral array phenotype had been previously observed in mitotic cells that were immunodepleted of the Eg5 motor protein.

The distinctive monoastral array phenotype facilitated identification of monastrol as a potential inhibitor of Eg5. Indeed, monastrol was further shown to inhibit the Eg5 motor-driven motility of microtubules in an *in vitro* assay. Furthermore, monastrol had no apparent effect upon the related kinesin motor or upon the motor(s) responsible for golgi apparatus movement within the cell. Cells that display the monoastral array phenotype, either through immunodepletion of Eg5 or monastrol inhibition of Eg5, arrest in M-phase of the cell cycle. Unfortunately, however, the mitotic arrest induced by either of these mechanisms is transient. (Kapoor, 2000. *J. Cell. Biol.* 150(5) 975-80). Both the monoastral array phenotype and the monastrol induced cell cycle arrest in mitosis are reversible. Cells recover to form a normal bipolar mitotic spindle, to complete mitosis, and to proceed through the cell cycle and normal cell proliferation. This suggests that a small molecule inhibitor of Eg5 that induced a transient mitotic arrest may not be effective for the treatment of

cancer cell proliferation. Nonetheless, the discovery that monastrol causes mitotic arrest is intriguing and hence there is a need to further study and identify compounds that can be used to modulate the Eg5 motor protein in a manner that would be effective in the treatment of human cancers. There is also a need to explore the use of these compounds in combination with other antineoplastic agents.

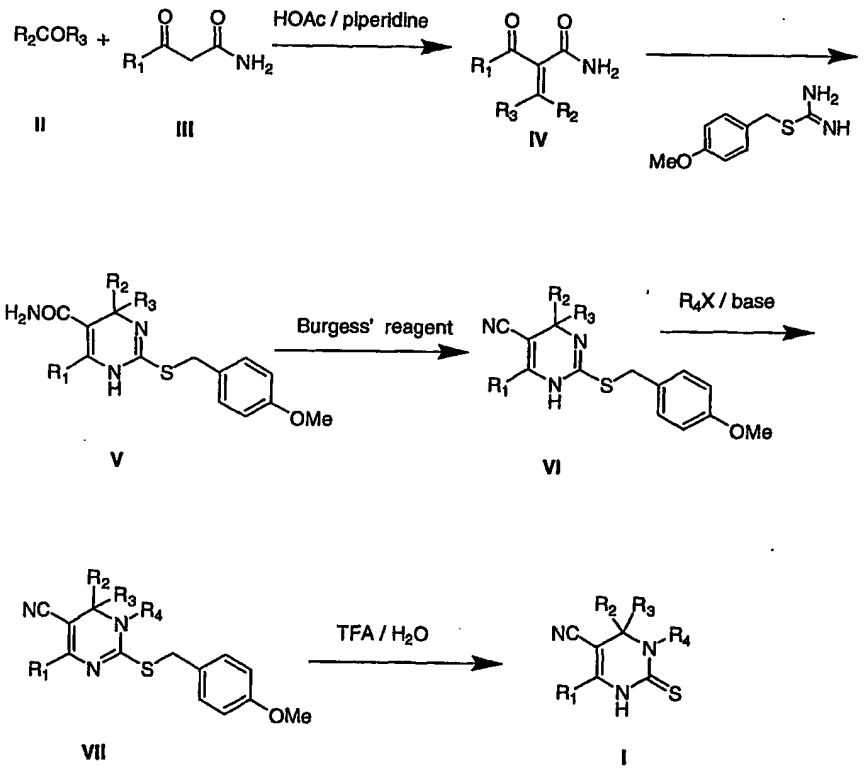
In another embodiment, the invention provides a method for treating a proliferative disease via modulation of the Eg5 motor protein comprising administering to a mammalian species in need of such treatment an effective amount of at least one compound of formula I or Ia, as defined above, in combination (simultaneously or sequentially) with at least one other anti-cancer agent. In a preferred embodiment, the proliferative disease is cancer.

Certain compounds of formula I may generally be prepared according to the following schemes and the knowledge of one skilled in the art. Solvates (e.g., hydrates) of the compounds of formula I and IA are also within the scope of the present invention. Methods of solvation are generally known in the art. Accordingly, the compounds of the instant invention may be in the free or hydrate form, and may be obtained by methods exemplified by the following schemes below.

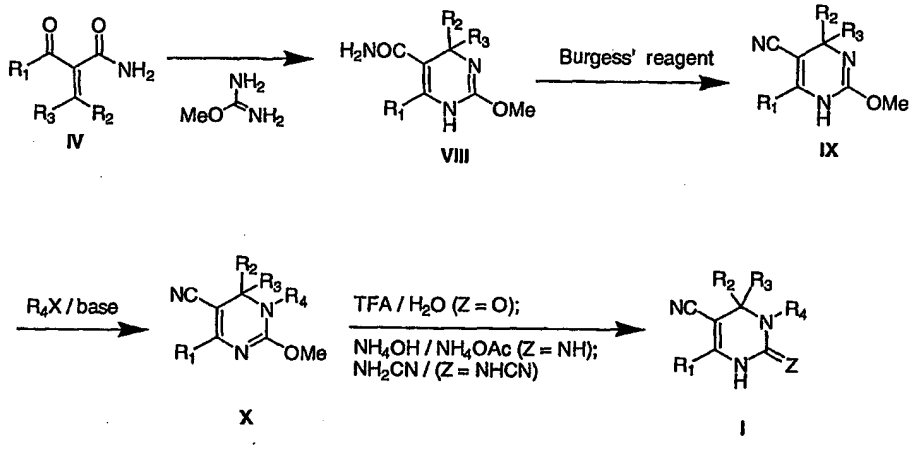
Scheme I



Compounds of formula I where Z is S may be made in accordance with Scheme I. A ketone or an aldehyde I (e.g., benzaldehyde, where R_2 is phenyl and R_3

is H), is condensed with an acetoacetamide III to give a Knoevenagel product IV as a mixture of isomers. Reaction with S-paramethoxybenzyl thiourea provides the protected dihydropyrimidine thione V. The primary amido group of V is dehydrated to the cyano substituent in VI using a dehydrating agent such as Burgess' reagent (methoxycarbonylsulfamoyl)triethylammonium hydroxide, inner salt. The N3 substituent is introduced by reaction with R_4X where R_4 is alkyl or acyl, and X is a leaving group, or where R_4X is an isocyanate or haloformate. The protecting group is removed by treatment with acid in the presence of water to give compounds of formula I where Z is S.

Scheme II

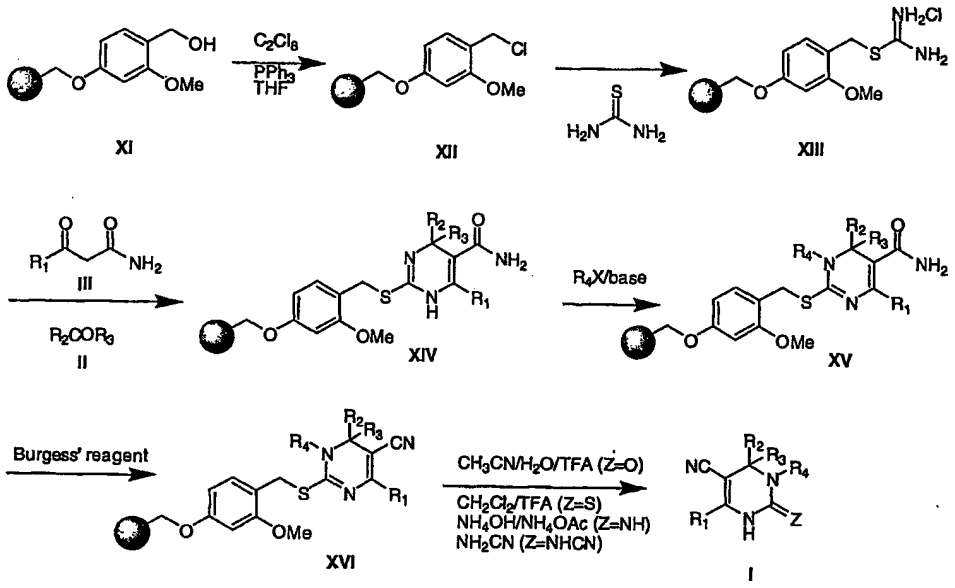


Compounds of formula I where Z is O, NH, or NR_8 are prepared from the reaction of Knoevenagel products IV with O-methyl isourea to provide the O-methyl dihydropyrimidines VIII. The primary amide is converted to a nitrile group using a dehydrating agent such as Burgess' reagent. The N3 substituent is introduced by reaction with R_4X where R_4 is alkyl or acyl, and X is a leaving group, or where R_4X is an isocyanate or haloformate. The methyl ether protecting group is removed by treatment with acid in the presence of water to give compounds of formula I where Z is O. Alternatively, treatment of compounds of formula X with ammonium hydroxide in the presence of ammonium acetate, or cyanamide in ethanol, provides compounds of formula I where Z is NH or NR_8.

Compounds of formula I may also be prepared using the Bignelli reaction (D. J. Brown in *The Pyrimidines*, Wiley: New York, 1962, 440).

Scheme III

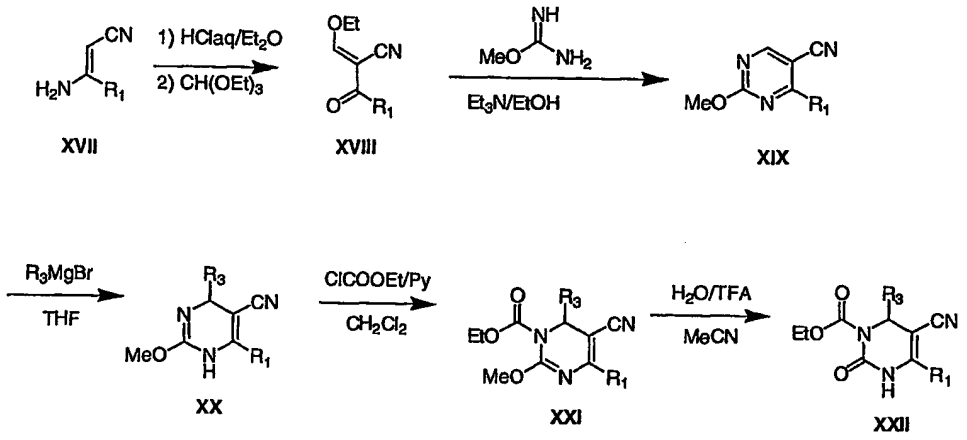
SOLID PHASE SYNTHESIS



Compounds of formula I could be prepared on solid support as outlined in Scheme III. Starting compound XI denotes a resin-bound benzyl alcohol used for solid support synthesis which is prepared from a Merrifield resin denoted as ●, and 2-methoxy-4-hydroxybenzaldehyde, followed by reduction of the aldehyde with reducing agents such as $NaBH_4$. The benzyl alcohol is converted into the benzyl chloride using agents such as hexachloroethane and triphenylphosphine in THF to form resins of formula XII. The chloride is displaced with thiourea to form the isothiourea resin XIII. The resulting resin is treated with excess of ketoamides like acetoamide (III, R_1 is CH_3), in the presence of ketones of formula R_2COR_3 or aldehydes of formula R_2CHO to form the resin-bound pyrimidinethiones of formula XIV. The N3 substituent is introduced using R_4X, where X is a leaving group and R_4 is alkyl or acyl, or R_4X is an isocyanate, or haloformate, in the presence of base to form structures of formula XV. The primary amide can be dehydrated to the cyano group using reagents such as Burgess' reagent to form compounds of formula XVI. The products can be cleaved from the resin using a variety of conditions to form compounds of formula I, where Z is determined by the cleavage method employed. Cleavage in the presence of aqueous acid will form compounds of formula I with Z being O, whereas cleavage under anhydrous acid conditions will form compounds of

formula I with Z being S. Alternatively, treatment of resins with structure XVI with ammonium hydroxide in the presence of ammonium acetate will form compounds of formula I with Z being NH, while treatment with cyanamide, provides compounds of formula I with Z being NHCN.

Scheme IV

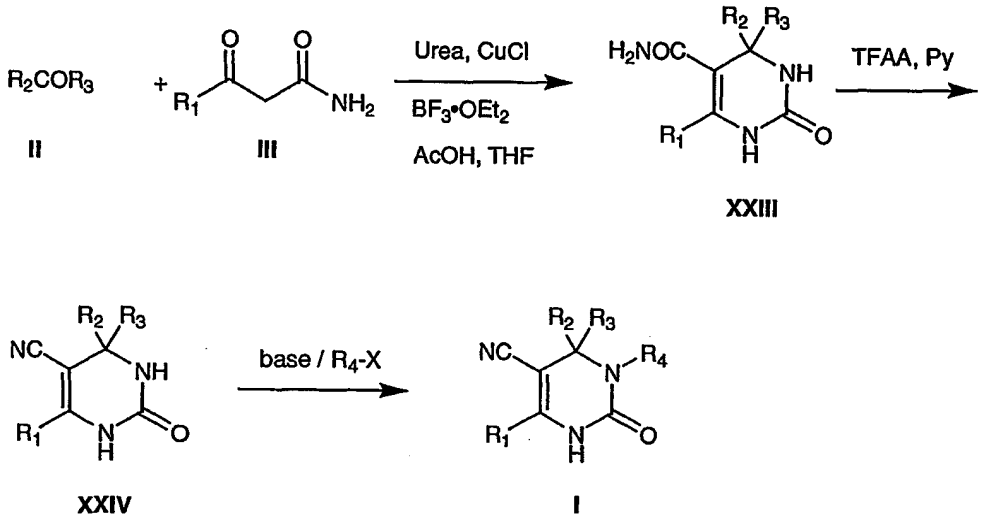


Compounds of formula XVIII may be prepared from a 3-amino-3-alkyl acrylonitrile XVII using the methods illustrated in Scheme IV. Reaction of a compound of formula XVII with aqueous acid, such as hydrochloric acid, followed by treatment with triethyl orthoformate, provides a compound of formula XVIII. Reaction of a compound of formula XVIII with O-methyl isourea in the presence of a base such as triethylamine, provides a pyrimidine of formula XIX. Pyrimidines of formula XIX may be reacted with organometallic species such as a Grignard reagent, R_3MgBr, in a solvent such as ether or tetrahydrofuran, to give a pyrimidine of formula XX, which is a compound of formula IX wherein R_2 is H. In analogy with Scheme II, a compound of formula XX may be converted into a compound of formula XXII, which is a compound of formula I in which R_4 is ethoxycarbonyl and R_2 is H.

Alternatively, compounds of formula I, wherein Z = O, may be prepared in accordance with Scheme V. Following the procedure of E.H. Hu *et al* (J. Org. Chem, **1998**, *63*, 3454-3457), a carbonyl compound of formula Ia is condensed with an acylacetamide of formula III in the presence of urea, cuprous chloride and borontriflouride etherate to give intermediate XXIII. Dehydration with trifluoroacetic anhydride in pyridine affords nitrile XXIV. The N3 substituent is introduced by

reaction with R_4X where R_4 is alkyl or acyl, and X is a leaving group, or where R_4X is an isocyanate or haloformate to give compounds of formula I. Deprotonation is effected with a base such as sodium hydride or LDA in aprotic solvents such as dimethylformamide or terahydrofuran.

Scheme V



In yet another procedure, compounds of formula I, wherein Z = O, may be prepared in accordance with Scheme VI. A carbonyl compound of formula II is condensed with an acylacetamide of formula III in the presence of urea and polyphospate ester to directly afford nitrile XXIV. Introduction of the N3 substituent follows the procedure as described in Scheme V. Compounds of formula I, where R_4 is aminocarbonyl, may also be obtained by first forming a reactive intermediate such as a nitrophenylcarbamate of formula XXV, which is subsequently reacted with an amine.

Scheme VI

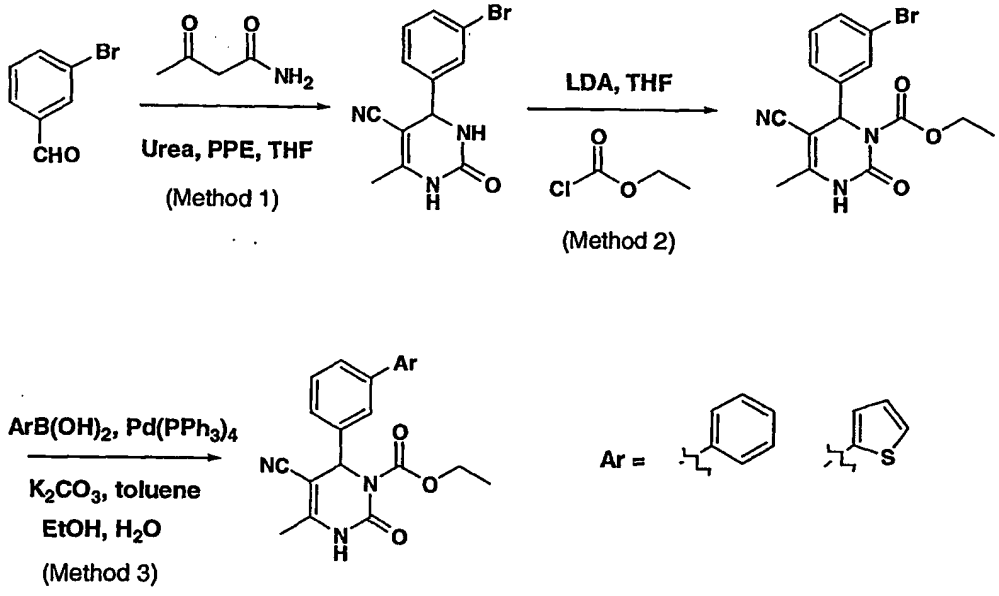
In all of the above schema, a 2-acyl acetonitrile derivative, i.e., R_1COCH_2CN, may be substituted for a compound of formula III.

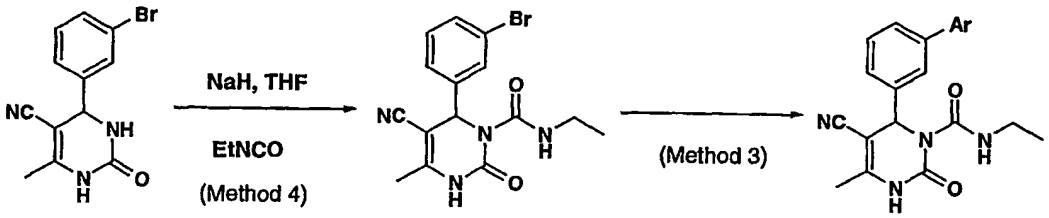
schemes below.

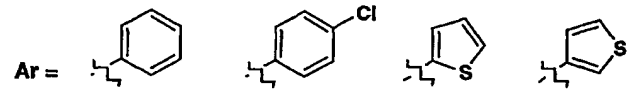
Scheme VII (Examples 116-117)



Compounds of formula Ia where R_4 is a carbamate may be made in accordance with Scheme VII. Following the procedure of Method 1, an appropriate aldehyde may be condensed with acetoacetamide and urea in the presence of polyphosphoric ester (PPE) to give a dihydropyrimidone product in high yield. Reaction of this compound with lithium diisopropylamide and ethyl chloroformate following the procedure of Method 2 provides predominately the N-1 carbamate, which then undergoes a palldium-catalyzed Suzuki coupling reaction with an aryl or heteroaryl boronic acid to give compounds of the present invention as described by Method 3.

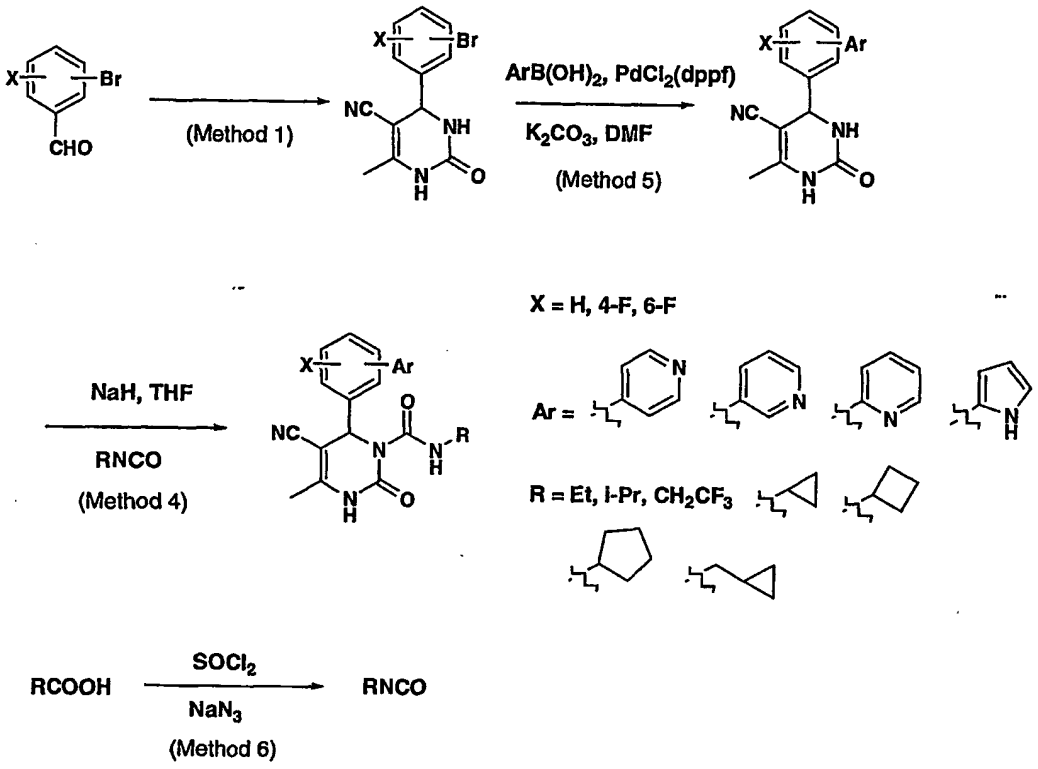
Scheme VIII (Examples 118-121)





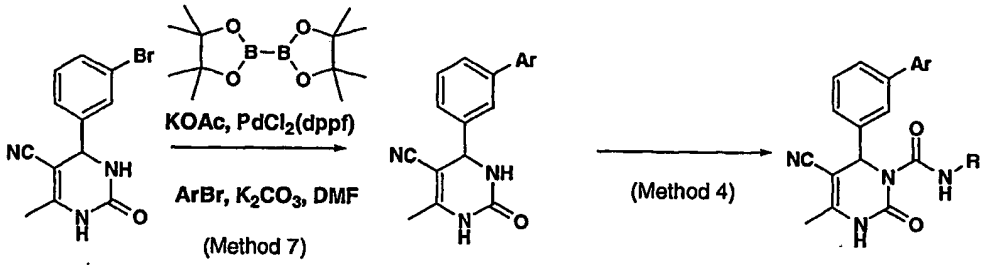
Similarly, compounds of formula Ia where R_4 is a urea may be made in accordance with Scheme VIII. Reaction of a dihydropyrimidone compound obtained following the procedure of Method 1 with sodium hydride and ethyl isocyanate following the procedure of Method 4 provides exclusively the N-1 urea, which then undergoes a palladium-catalyzed Suzuki coupling reaction with an aryl or heteroaryl boronic acid to give compounds of the present invention as described by Method 3.

Scheme IX (Examples 122-139, 144-145)



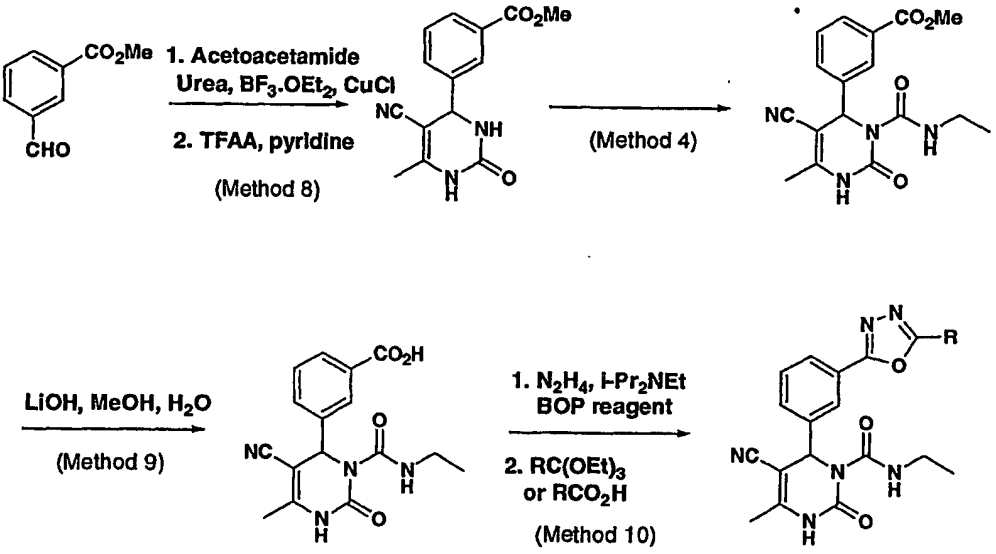
An alternative reaction sequence is described in Scheme IX, wherein a palladium-catalyzed coupling reaction may be performed prior to addition of the exocyclic urea moiety at the N-1 position on the dihydropyrimidone ring. Thus, the dihydropyrimidone product of Method 1 may be reacted with an appropriate aryl or heteroaryl boronic acid in the presence of a palladium catalyst following Method 5 to afford a biaryl product. Subsequent reaction with an isocyanate in the presence of sodium hydride following the procedure of Method 4 affords the compounds of the present invention in good yield. A variety of isocyante reagents may be prepared from corresponding carboxylic acid precursors by treatment with thionyl chloride and sodium azide using Method 6.

Scheme X (Examples 140-141)



A variation of the process of Scheme IX involves formation of the boronic acid derivative of the dihydropyrimidone prepared by Method 1 and is described in Scheme X. This boronic acid derivative may be prepared by reaction of an appropriate aryl halide with bis(pinacolato)diboron in the presence of a palladium catalyst. Subsequent reaction with an appropriate aryl halide in the presence of additional palladium catalyst affords the desired biaryl compound following the procedure of Method 7. Subsequent reaction with an isocyanate in the presence of sodium hydride following the procedure of Method 4 affords the compounds of the present invention in good yield.

Scheme XI (Examples 142-143)



Oxadiazole-substituted compounds of formula IA may be prepared in accordance with Scheme X. Following the procedure of Method 8, an appropriate aryl aldehyde may be condensed with acetoacetamide and urea in the presence of boron trifluoride, followed by dehydration with trifluoroacetic anhydride to give a dihydropyrimidone compound. Reaction of this dihydropyrimidone with an isocyanate and sodium hydride following the procedure of Method 4 affords the N-1 substituted urea, which may be further reacted with lithium hydroxide to provide a carboxylic acid as described by Method 9. Treatment of the carboxylic acid with hydrazine and BOP reagent affords the corresponding acyl hydrazide, which undergoes cyclization with triethyl orthoacetate or an alkyl acid to afford compounds of the present invention as described by Method 10

As discussed in the background section, Eg5 is a kinesin-like motor protein that facilitates spindle bipolarity during mitosis of the cell cycle. More specifically, the Eg5 protein acts to sort and bundle microtubules of the mitotic spindle during mitosis. Accordingly, Eg5 participates in cell cycle regulation through the spindle checkpoint during the M phase of the cycle. While not wishing to be bound by any theory, it is believed that the compounds of the instant invention act as Eg5 inhibitors. This is theorized because the compounds of the instant invention induce a monopolar astral array of microtubules (the monoastral phenotype) and it has been shown that when Eg5 activity is absent, the monoastral phenotype forms. Regardless of the mechanism of action, the compounds of the instant invention have been shown to cause disruption of the bipolar spindle, spindle checkpoint initiation, mitotic arrest, programmed cell death and tumor cell proliferation inhibition. Furthermore, the compounds of the invention induce a cell cycle arrest in mitosis that is not transient but rather which progresses into programmed cell death. The compounds also exhibit high potency, inducing mitotic arrest and apoptosis in human cells *in vitro* at concentrations in the low or sub μM range. Additionally, in contrast to microtubule agents, the compounds do not disrupt the dynamic instability of microtubules. The instant invention may therefore more specifically target the mitotic spindle of proliferating cells, which may provide for different toxicity profiles than those of existing anti-cancer drugs.

The compounds according to the invention have pharmacological properties; in particular, the compounds of formula I induce mitotic arrest and are believed to be Eg5 inhibitors. The novel compounds of formula I are thus useful in the therapy of a variety of proliferative diseases (including but not limited to diseases associated with the Eg5 motor protein) such as cancer, autoimmune diseases, viral diseases, fungal diseases, neurodegenerative disorders and cardiovascular disease.

More specifically, the compounds of formula I are useful in the treatment of a variety of cancers, including, but not limited to, the following:

a) carcinoma, including that of the bladder, breast, colon, kidney, liver, lung, including small cell lung cancer, esophagus, gall bladder, ovary, pancreas, stomach, cervix, thyroid, prostate, and skin, including squamous cell carcinoma;

b) hematopoietic tumors of lymphoid lineage, including leukemia, acute lymphocytic leukemia, acute lymphoblastic leukemia, B-cell lymphoma, T-cell lymphoma, Hodgkins lymphoma, non-Hodgkins lymphoma, hairy cell lymphoma and Burkett's lymphoma;

c) hematopoietic tumors of myeloid lineage, including acute and chronic myelogenous leukemias, myelodysplastic syndrome and promyelocytic leukemia;

d) tumors of mesenchymal origin, including fibrosarcoma and rhabdomyosarcoma;

e) tumors of the central and peripheral nervous system, including astrocytoma, neuroblastoma, glioma and schwannomas; and

f) other tumors, including melanoma, seminoma, teratocarcinoma, osteosarcoma, xenoderoma pigmentosum, keratoctanthoma, thyroid follicular cancer and Kaposi's sarcoma.

Due to the key role of motor proteins in the regulation of cellular proliferation in general, inhibitors could act as reversible cytostatic agents which may be useful in the treatment of any disease process which features abnormal cellular proliferation, e.g., benign prostatic hyperplasia, familial adenomatosis polyposis, neuro-fibromatosis, atherosclerosis, pulmonary fibrosis, arthritis, psoriasis, glomerulo-nephritis, restenosis following angioplasty or vascular surgery, hypertrophic scar

formation, inflammatory bowel disease, transplantation rejection, endotoxic shock, and fungal infections.

Compounds of formulae I and Ia induce apoptosis. The apoptotic response is aberrant in a variety of human diseases. Compounds of formula I, as modulators of apoptosis, will be useful in the treatment of cancer (including but not limited to those types mentioned herein above), viral infections (including but not limited to herpevirus, poxvirus, Epstein-Barr virus, Sindbis virus and adenovirus), prevention of AIDS development in HIV-infected individuals, autoimmune diseases (including but not limited to systemic lupus, erythematosus, autoimmune mediated glomerulonephritis, rheumatoid arthritis, psoriasis, inflammatory bowel disease, and autoimmune diabetes mellitus), neurodegenerative disorders (including but not limited to Alzheimer's disease, AIDS-related dementia, Parkinson's disease, amyotrophic lateral sclerosis, retinitis pigmentosa, spinal muscular atrophy and cerebellar degeneration), myelodysplastic syndromes, aplastic anemia, ischemic injury associated with myocardial infarctions, stroke and reperfusion injury, arrhythmia, atherosclerosis, toxin-induced or alcohol related liver diseases, hematological diseases (including but not limited to chronic anemia and aplastic anemia), degenerative diseases of the musculoskeletal system (including but not limited to osteoporosis and arthritis) aspirin-sensitive rhinosinusitis, cystic fibrosis, multiple sclerosis, kidney diseases and cancer pain.

Compounds of formula I and Ia may modulate the level of cellular RNA and DNA synthesis. These agents would therefore be useful in the treatment of viral infections (including but not limited to HIV, human papilloma virus, herpesvirus, poxvirus, Epstein-Barr virus, Sindbis virus and adenovirus).

Compounds of formula I and Ia may be useful in the chemoprevention of cancer. Chemoprevention is defined as inhibiting the development of invasive cancer by either blocking the initiating mutagenic event or by blocking the progression of pre-malignant cells that have already suffered an insult or inhibiting tumor relapse.

Compounds of formula I may also be useful in inhibiting tumor angiogenesis and metastasis.

The instant invention may also inhibit other motor proteins, for example, including but not limited to: those human motor proteins that correspond to, Xklp2,

MKLP1, CHO1, chromokinesins, Nod, Cenp-E, MCAK, members of the BimC family, and members of the Kar3 family. Additionally, compounds used in the methods of the instant invention may also act as inhibitors of other kinesin or kinesin-like proteins and thus be effective in the treatment of diseases associated with other kinesin or kinesin-like proteins.

The compounds of this invention may also be useful in combination (administered together or sequentially) with known anti-cancer treatments such as radiation therapy or with cytostatic or cytotoxic agents, such as for example, but not limited to, DNA interactive agents, such as cisplatin or doxorubicin; topoisomerase II inhibitors, such as etoposide; topoisomerase I inhibitors such as CPT-11 or topotecan; tubulin interacting agents, such as paclitaxel, docetaxel or the epothilones, eitehr naturally occurring or synthetic; hormonal agents, such as tamoxifen; thymidilate synthase inhibitors, such as 5-fluorouracil; and anti-metabolites, such as methoxtrexate.

If formulated as a fixed dose, such combination products employ the compounds of this invention within the dosage range described below and the other pharmaceutically active agent or treatment within its approved dosage range. Compounds of formulae I and Ia may also be administered sequentially with known anticancer or cytotoxic agents when a combination formulation is inappropriate. The invention is not limited in the sequence of administration; compounds of formulae I and Ia may be administered either prior to or after administration of the known anticancer or cytotoxic agent(s).

ASSAYS

The pharmacological properties of the compounds of this invention may be confirmed by a number of pharmacological assays. The exemplified pharmacological assays which follow have been carried out with the compounds according to the invention and their salts. The compounds of formulae I and Ia exhibited antiproliferative activity. Preferred compounds exhibit IC_{50} values less than or equal to about 10 μM.

Cell Culture

Cell lines are maintained in RPMI-1640 plus 10% fetal bovine serum.

72-Hour Proliferation Assay

Cells were plated at a density of 3,000-6,000 cells/well, depending upon the cell line used, in a 96-well plate. The cultures were grown overnight. Cells were then treated in triplicate with a seven concentration dose-response curve. The maximum concentration of DMSO never exceeded 0.5%. Cells were exposed to compound for 72 hours. Proliferation was measured using XTT or MTS from Promega. The ovarian, breast, prostate, lung, leukemia, and colorectal human cancer cell lines used in this assay included but were not limited to, for example, A2780S, SKBR3, MDA-MB-231, PC3, LX-1, K562, HT-29, WiDr, HCT-15 and HCT116. The compounds of formula I exhibited activity in the 72-hour cell proliferation assay, inhibiting cell proliferation in one or more of the cell lines listed above with at an IC_{50} less than or equal to about 10 μM.

Clonogenic Growth Assay

Colony growth inhibition was measured for A2780 ovarian carcinoma cells using a standard clonogenic assay. Briefly, 200 cells/well were seeded into 6-well tissue culture plates (Falcon, Franklin Lakes, NJ) and allowed to attach for 18 hours. Assay medium consisted of RPMI-1640 plus 10% fetal bovine serum. Cells were then treated in duplicate with a six concentration dose-response curve. The maximum concentration of DMSO never exceeded 0.25%. Cells were exposed to compound for 4, 8 or 24 hours. Compound was then removed and the cells were washed with 2 volumes of PBS. The normal growth medium was then replaced. Colonies were fed with fresh media every third day. Colony number was scored on day 10-14 using a Optimax imaging station. The compound concentration required to inhibit 50% or 90% of colony formation (IC_{50} or IC_{90}, respectively) was determined by non-linear regression analysis. The coefficient of variance (SD/mean, n=3) = 30%. When exposed to cells for 24 hours, the compounds of formulae I and IA exhibited activity in the clonogenecity assay.

Combination Studies - Clonogenic Growth Assays

Combination studies to examine the use of the Eg5 inhibitors of formulae I and Ia in combination with other antineoplastic agents were conducted essentially the same as the standard colony growth assay with the exception of compound treatment. In the combination studies, the cells were treated with both a compound of formulae I and Ia and another antineoplastic agent. The compounds were administered simultaneously or sequentially; both the order of sequence and length of treatment (1 to 24 hours) were varied. Data evaluation was based upon the isobologram analysis and the envelope of additivity, using the line of multiplicity which compares the survival fractions of combination treatments with those of single drug treatments.

Cell Cycle Analysis

The cell cycle profile of cells treated with compounds of formulae I and Ia was monitored by flow cytometry. Briefly, A2780 ovarian carcinoma cells were seeded at a density of 2×10^5 per well in standard 6 well culture plates and permitted to grow for 17 hours. Cells were then exposed to compounds of formulae I and Ia at varying concentrations for 2 to 24 hours. Following exposure, cell populations were harvested, stained with propidium iodide to determine DNA content and also stained with the appropriate immunological reagent for protein biomarkers of mitosis and apoptosis, including, for example, anti-phospho-ThreonineProline, anti-M Phase Phospoprotein 2 (MMP2), and anti-p85 PARP. The compounds of formulae I and IA exhibited activity in the cell cycle profile analysis assay, producing significant increases in mitotic and apoptotic fractions of the cell population.

Immunocytochemistry Assays

A2780 ovarian carcinoma cells or PTK2 kangaroo rat kidney epitheilal cells were plated at a density of 200 to 2000 cells per well in 4 chamber glass slides and allowed to attach overnight. Cells were then treated with compounds of formula I and II, separately, at concentrations of 100 nM to 50 μM for 4 to 30 hours, fixed and permeabilized for subsequent staining. Stain reagents included, for example, propidium iodide, DAPI, rhodamine phalloidin, anti-αtubulin, anti-βtubulin, anti-γtubulin, and the appropriate fluorescent-tagged secondary antibodies. Cells were

imaged by fluorescent and confocal fluorescent microscropy. The compounds of formulae I and IA inhibited bipolar spindle formation and induced a monoastral array of microtubules.

Further subject matter of the invention also includes pharmaceuticals for use as described above including controlling cancer, inflammation and arthritis, which contain at least one compound of formula I or IA as defined above or at least one of its pharmacologically acceptable acid addition salts, and the use of a compound of the formula I or IA as defined above for the preparation of a pharmaceutical having activity against proliferative diseases as described previously including against cancer, inflammation and/or arthritis.
